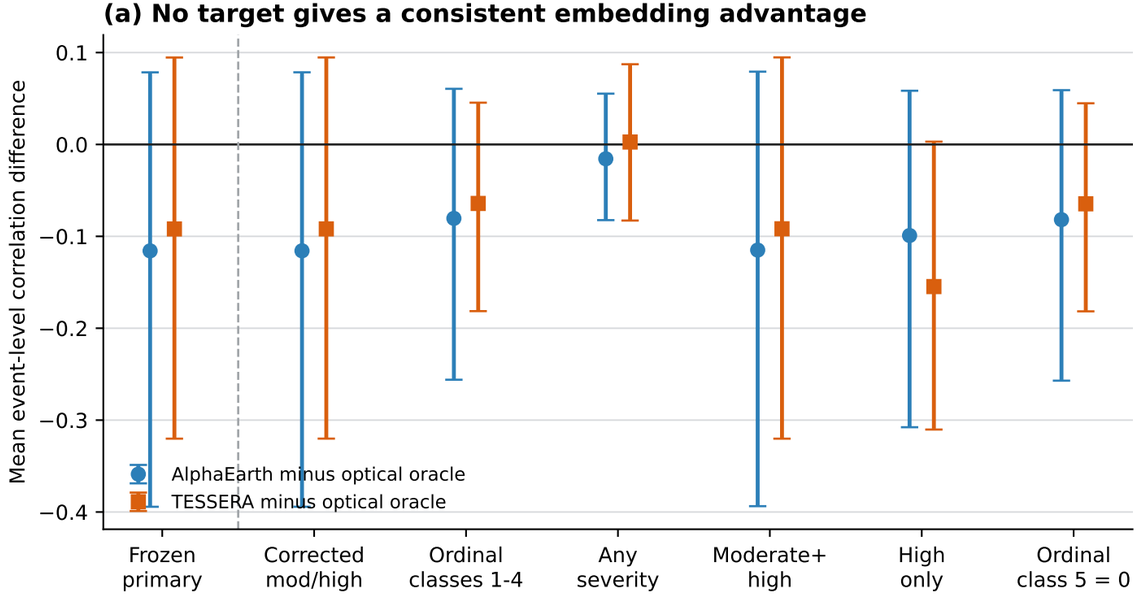
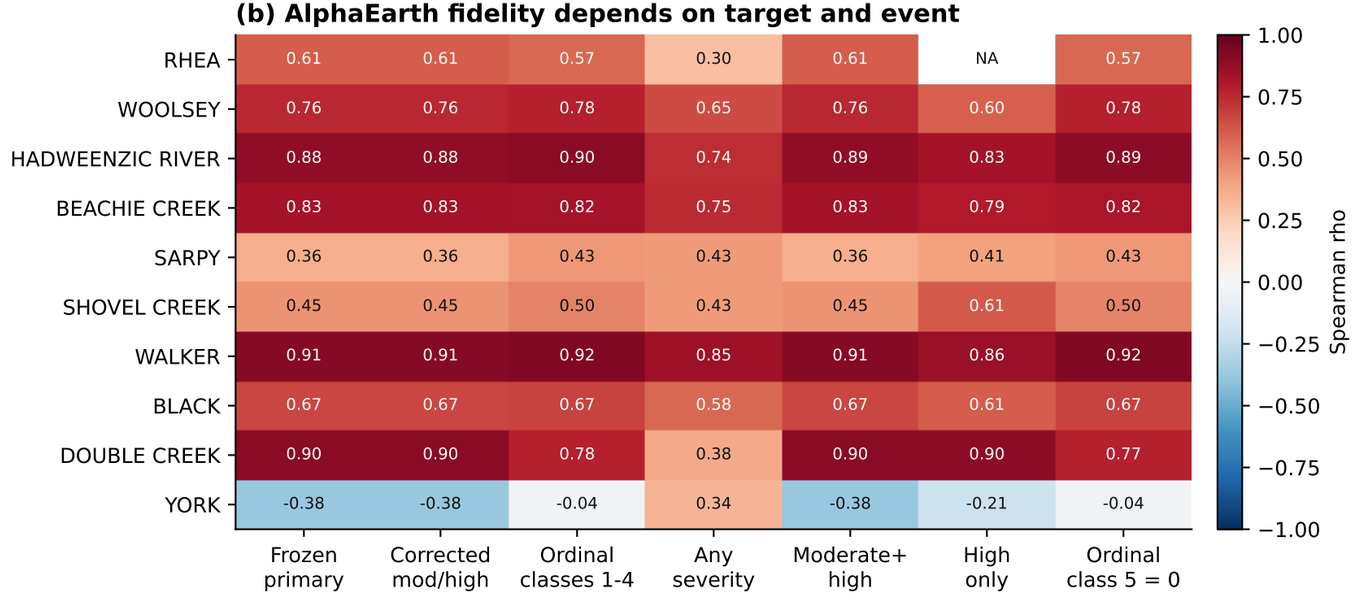
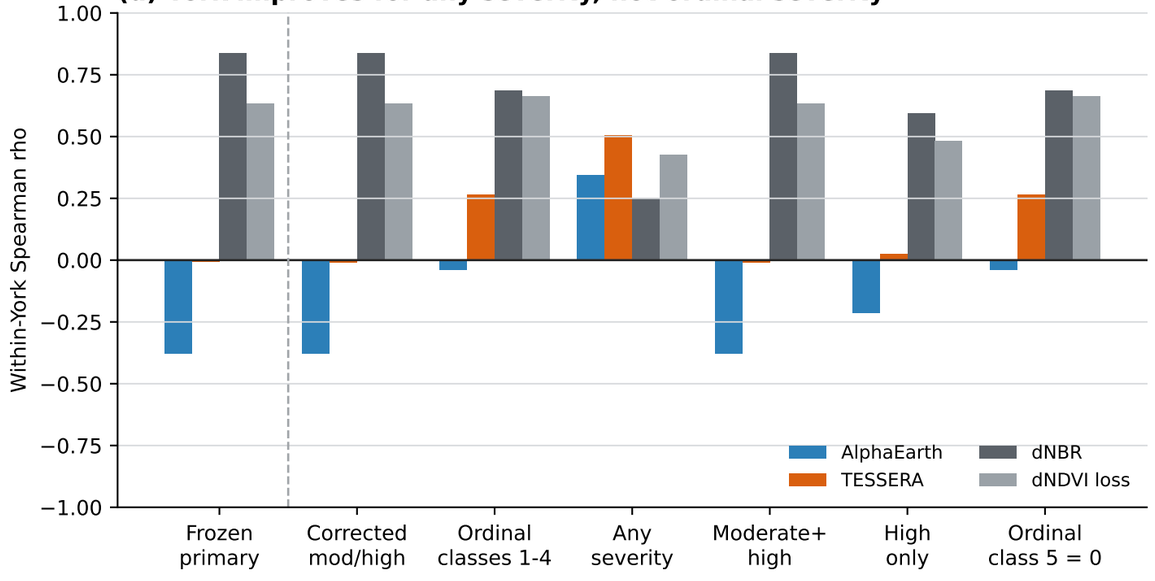
Post hoc MTBS target diagnostic on the frozen ten-fire cohort

Original targets were frozen before their first recomputation. A corrected moderate/high target was mandated after a raster-window audit. The sealed endpoint remains primary.







Points and intervals in (a) summarize fires, not cells (100,000 event bootstrap resamples). Each optical oracle is recomputed for the same target. The second column corrects the raster-window edge; the final column tests class-5 handling.
